

ASVIO Bank accelerates financial monitoring with Claude

The SoftBees AI Agent, deployed at ASVIO Bank with Techlegion as Delivery Partner of Record, reduced specialist review time for a large bank statement from 11.5 hours to approximately one hour.

Anthropic: Claude provider

Techlegion: Delivery Partner of Record

Softbees: Customer / intermediary, depending on contract

ASVIO Bank: End customer / deployment user

Industry: Banking / Financial Services **Status:** Live in production

The challenge

Statements submitted for financial monitoring typically run 40-90 pages and arrive in more than ten layouts, including text PDFs, spreadsheets, scans and phone photographs. Without a common structure across banks, specialists had to extract and check each document manually. One large statement required around 11.5 hours of work, creating a bottleneck and increasing the risk of errors during repetitive review.

What SoftBees built

The SoftBees AI Agent reconstructs transaction tables, validates the extracted data and supports the first level of AML review. It produces an explainable risk assessment: findings cite the relevant transaction rows and identify what the compliance officer should verify. The officer retains responsibility for the final decision.

Why Claude

SoftBees compared models using real banking documents. In the team's tests, local open-source models without fine-tuning struggled with Ukrainian banking identifiers, including MFO bank routing codes and EDRPOU company registration numbers. Claude produced the required structured results without fine-tuning, helping the team meet the implementation timeline. The solution uses **Claude 3.7 Sonnet through the Amazon Bedrock API**.

Results at ASVIO Bank

Measure	Reported result
Specialist time per large statement	11.5 hours to approximately 1 hour More than 90% less time
Production usage	4,000+ documents during 2025-2026
Cost per document case	17-fold reduction , reported by the bank

The time comparison refers to the measured large-statement workflow. Production volume covers 2025-2026. Cost reduction is a customer-reported result.

How the solution works

SoftBees designed three processing paths, using Claude where document complexity requires it.

1. Text PDFs: deterministic extraction. A Java parser reads the PDF's text layer and table geometry without a model call. This provides a direct path for documents that already contain usable text.

2. Text PDFs with Claude post-processing. When post-processing is enabled, Claude receives the page image and extracted rows. It repairs issues such as values split across lines within a cell, unidentified counterparty codes and truncated payment descriptions.

3. Scans and photographs: visual extraction. Claude reads pages directly, with one call per page in parallel. Pages can be divided into bands to retain the resolution needed to recognise transaction details and digits.

Validation and human review

All paths normalise identifiers, verify IBANs using the mod-97 checksum and reconcile totals against the statement. Rule-based AML analysis then checks nine categories. Each finding links back to transaction evidence and gives the officer a next verification step. Structured outputs are available as JSON through an API or as XLSX.

Processing and deployment

The team reports processing times of 1-2 seconds for spreadsheets and text-layer PDFs, and 60-90 seconds for scans and photographs. These are automated processing times, separate from the approximately one-hour specialist review workflow. The application can run in the cloud or within bank infrastructure as a Docker container or Java JAR; Claude inference uses the Amazon Bedrock API.

The customer's perspective

“We have effectively eliminated human error; we cut the processing time for a single document by 90%, from 11.5 hours to one hour; and we reduced the cost of processing a case of documents seventeen-fold.”

Yevhen Shulika, Chairman of the Board, ASVIO Bank
